Abstract. In this paper, we survey the nature of spinors and supersymmetry (SUSY) in various types of spaces. We treat two distinct types of spaces: flat spaces and spaces of constant (non-zero) curvature. The flat spaces we consider are either three or four dimensional of signatures $3 + 1$, $4 + 0$, $2 + 2$ and $3 + 0$. In each of these cases, SUSY generators anti-commute to yield the generators of translations in the non-compact flat spaces. The spaces of constant curvature we consider are two-dimensional: the surface of the sphere S_2 and the Anti-deSitter space AdS_2 . S_2 is embedded in a $3 + 0$ Euclidean space while AdS_2 is embedded in $2 + 1$ Minkowski space. The SUSY generators in these cases anti-commute to yield the generators of the isometry groups ($SO(3)$ or $SO(2, 1)$) of the space involved.

We also report on some recent developments in looking for superspace realizations of these SUSY algebras. We can report good progress in the $3 + 0$ Euclidean and in the AdS_2 case, somewhat less in the S_2 case. In each of the compact cases, we can construct field multiplet models carrying invariance under the full SUSY algebra.

1 Flat Space SUSY Analysis

1.1 $3 + 1$ Dimensions

The analysis of spinors and supersymmetry (SUSY) in three dimensional Minkowski space is quite standard. (See for example ref. [1].) In a representation in which Dirac matrices are given by

$$\gamma^\mu = \left[\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \begin{pmatrix} 0 & \vec{\sigma} \\ -\vec{\sigma} & 0 \end{pmatrix} \right] \quad (1)$$

and a charge conjugation matrix C is defined by

$$C^{-1} \gamma^\mu C = -\gamma^{\mu T}, \quad (2)$$

we have spinors

$$\Psi = \begin{pmatrix} \psi_\alpha \\ \bar{\chi}^{\dot{\alpha}} \end{pmatrix} \quad \bar{\Psi} \equiv \Psi^\dagger \gamma^0 = (\chi^\alpha, \bar{\psi}_{\dot{\alpha}}) \quad (3a)$$

and

$$\Psi_C \equiv C\bar{\Psi}^T = \begin{pmatrix} \chi_\alpha \\ \bar{\psi}^{\dot{\alpha}} \end{pmatrix} \quad \bar{\Psi}_C = (\psi^\alpha, \bar{\chi}_{\dot{\alpha}}) \quad (3b)$$

forming representations of the Lorentz group. The spinorial generator Q of the $N = 1$ extension of the Poincaré group is Majorana (ie, $Q = Q_C = \begin{pmatrix} Q_\alpha \\ \bar{Q}^{\dot{\alpha}} \end{pmatrix}$) and satisfies the algebra

$$\{Q_\alpha, Q_\beta\} = 0 \quad (4a)$$

$$\{Q_\alpha, \bar{Q}_{\dot{\beta}}\} = 2\sigma_{\alpha\dot{\beta}}^\mu P_\mu. \quad (4b)$$

The two spinorial generators of $N = 2$ SUSY extension of the Poincaré group are both Majorana (ie, $Q_i = Q_{Ci}$ for $i = 1, 2$) and satisfy the algebra

$$\{Q_\alpha^i, \bar{Q}_{\dot{\beta}j}\} = 2\delta_j^i \sigma_{\alpha\dot{\beta}}^\mu P_\mu \quad (5a)$$

$$\{Q_\alpha^i, Q_\beta^j\} = \epsilon_{\alpha\beta} \epsilon^{ij} Z \quad (5b)$$

incorporating a central charge Z which commutes with all the other generators of this algebra. A representation of this algebra can be found using Fermionic creation and annihilation operators

$$a_\alpha = \frac{1}{\sqrt{2}} (Q_\alpha^1 + \epsilon_{\alpha\beta} Q_\beta^{2\dagger}), \quad b_\alpha = \frac{1}{\sqrt{2}} (Q_\alpha^1 - \epsilon_{\alpha\beta} Q_\beta^{2\dagger}). \quad (6)$$

From (5) it follows that

$$\{a_\alpha, a_\beta^\dagger\} = \delta_{\alpha\beta} (2M + Z) \quad (7a)$$

$$\{b_\alpha, b_\beta^\dagger\} = \delta_{\alpha\beta} (2M - Z) \quad (7b)$$

in a frame in which $P_\mu = (M, \vec{0})$. By (7b) we obtain the “BPS” bound

$$2M \geq Z. \quad (8)$$

1.2 4 + 0 Dimensions

The situation in four dimensional Euclidean space is quite different. In this case

$$\gamma^\mu = \left[\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \begin{pmatrix} 0 & i\vec{\sigma} \\ -i\vec{\sigma} & 0 \end{pmatrix} \right] \quad (9)$$

so that

$$\Psi = \begin{pmatrix} \psi_\alpha \\ \chi^{\dot{\alpha}} \end{pmatrix} \quad \bar{\Psi} = \Psi^\dagger = (\bar{\psi}^\alpha, -\bar{\chi}_{\dot{\alpha}}) \quad (10a)$$

and

$$\Psi_C = C\bar{\Psi}^T = \begin{pmatrix} -\bar{\psi}_\alpha \\ \bar{\chi}^{\dot{\alpha}} \end{pmatrix} \quad \bar{\Psi}_C = (\psi^\alpha, \chi_{\dot{\alpha}}) \quad (10b)$$

for representations of $SO(4) = SU(2) \times SU(2)$. The spinor ψ_α transforms under one $SU(2)$ subgroup while χ^α transforms under the other $SU(2)$ subgroup. It is also evident from (10) that as $(\bar{\Psi}_C)_C = -\Psi$, we cannot have Majorana spinors in $4 + 0$ dimensions. The simplest self conjugate SUSY algebra is now [2]

$$\{Q_a, \bar{R}_b\} = i\sigma_{ab}^\mu P_\mu \quad \{Q_a, R_b\} = 0 \quad (11a, b)$$

$$\{Q_a, \bar{Q}_b\} = \epsilon_{ab} Z_{Q\bar{Q}} \quad \{R^a, \bar{R}^b\} = \epsilon^{ab} Z^{R\bar{R}} \quad (11c, d)$$

or, equivalently, if we define

$$G = \begin{pmatrix} Q_a \\ R^{\dot{a}} \end{pmatrix} \Rightarrow \begin{matrix} S_{a1} = Q_a & S_{a2} = \bar{Q}_a \\ T_{\dot{a}1} = -R_{\dot{a}} & T_{\dot{a}2} = \bar{R}_{\dot{a}} \end{matrix} \quad (12)$$

we obtain an equivalent algebra which displays an $SU(2)$ structure

$$\{S_{ai}, S_{bj}\} = \epsilon_{ab}\epsilon_{ij} Z_{Q\bar{Q}} \quad (13a)$$

$$\{T_{\dot{a}i}, T_{\dot{b}j}\} = \epsilon_{\dot{a}\dot{b}}\epsilon_{ij} Z^{R\bar{R}} \quad (13b)$$

$$\{S_{ai}, T_{\dot{b}j}\} = i\epsilon_{ij}\sigma_{ab}^\mu P_\mu. \quad (13c)$$

This is similar in form to (5) with the roles of Z and P^μ “reversed”. Thus the simplest SUSY extension of the $ISO(4)$ group in $4 + 0$ dimensions is an $N = 2$ algebra. This algebra when rewritten in terms of Fermionic creation and annihilation operators becomes, in the frame where $P^\mu = (0, 0, 0, P)$,

$$\{A_a, A_b^\dagger\} = \delta_{ab} \left[1 + P \left(Z_{Q\bar{Q}} Z^{R\bar{R}} \right)^{-1/2} \right] \quad (14a)$$

$$\{B_a, B_b^\dagger\} = \delta_{ab} \left[1 - P \left(Z_{Q\bar{Q}} Z^{R\bar{R}} \right)^{-1/2} \right]. \quad (14b)$$

We hence see that $P = \sqrt{P_\mu P_\mu}$ has an upper bound in $4 + 0$ dimensions if the Hilbert space is to be positive definite,

$$P \leq \left(Z_{Q\bar{Q}} Z^{R\bar{R}} \right)^{1/2}. \quad (15)$$

As in $3 + 1$ dimensions, saturating the bound eliminates one half of the states.

An important distinction between $N = 2$ SUSY in Minkowski space and $N = 2$ SUSY in Euclidean space can now be drawn. In $3 + 1$ space the central charge provides a lower bound on the magnitude of the momentum, of the mass associated with the state. The lower bound can be zero; there is no inconsistency in considering zero central charge. In $4 + 0$ space on the other hand, the central charge provides an upper bound on the magnitude of the momentum. Such an upper bound on a positive definite quantity $\sqrt{P_\mu P_\mu}$ cannot be zero; the case of a zero central charge can only lead to all states having zero momentum yielding a trivial theory. We conclude that in $4 + 0$ space we must include a central charge.

A similar upper bound on momentum arises when one has extended SUSY in $4 + 0$ dimensions with algebra [3]

$$\{Q_{ai}, \overline{Q}_{bj}\} = \epsilon_{ab} Z_{ij}^Q \quad (16a)$$

$$\{R_{\dot{a}i}, \overline{R}_{\dot{b}j}\} = \epsilon_{\dot{a}\dot{b}} Z_{ij}^R \quad (16b)$$

$$\{Q_{ai}, \overline{R}_{\dot{b}j}\} = i\sigma_{\dot{a}\dot{b}}^\mu \epsilon_{ij} P^\mu. \quad (16c)$$

Just as $N = 2$ super Yang-Mills theory in $3 + 1$ dimensions can be obtained by dimensional reduction of the $N = 1$ gauge theory in $5 + 1$ dimensions, so also the supersymmetric gauge model of Zumino in $4 + 0$ dimensions can be generated; it has the action

$$S = \int d^4 x_E \left[-\frac{1}{4} F_{\mu\nu}^2 + \frac{1}{2} (D_\mu A)^2 - \frac{1}{2} (D_\mu B)^2 - \frac{i}{2} (\psi^\dagger \gamma \cdot \overleftrightarrow{D} \psi) \right. \\ \left. + ig \psi^\dagger (A - B \gamma_5) \psi + \frac{1}{2} g^2 (A \times B)^2 \right]. \quad (17)$$

One simply drops dependence on one space variable and the time variable in the $5 + 1$ dimensional model and has the corresponding components of the vector field identified with the scalar fields A and B . Explicit calculation [4] shows that the β -function in this model is the same as that in $N = 2$ gauge theory in $3 + 1$ dimensions despite the peculiar kinetic terms in (16) for the scalars A and B .

A model with extended SUSY invariance in $4 + 0$ dimensions can be obtained by dimensional reduction of $N = 1$ gauge theory in $9 + 1$ dimensions. It is expected that the β -function in this model vanishes, just as it does for $N = 4$ gauge theory in $3 + 1$ dimensions, thereby ensuring that conformal invariance is unbroken.

The $SU(2)$ structure of (12) allows one to define a Harmonic superspace in conjunction with $4 + 0$ dimensions [5]. This allows for off-shell realization of this symmetry in these models.

We also note that in $4 + 0$ dimensions, one can define a model which is (a) Hermitian (b) gauge invariant under an axial $U(1)$ gauge transformation (c) anomaly free. Its action is

$$S = \int d^4 x_E \left(\frac{1}{4} F_{\mu\nu}(A) F_{\mu\nu}(A) + \Psi_C^\dagger (\not{p} + \not{A} \gamma_5) \Psi + \Psi^\dagger (\not{p} - \not{A} \gamma_5) \Psi_C \right). \quad (18)$$

No analogue of this model can be defined in $3 + 1$ dimensions.

The usual form of the actions considered in 4dE are

$$L^{(1)} = \frac{1}{4} F_{\mu\nu}(A) F_{\mu\nu}(A) + \Psi^\dagger (\not{p} + \not{A} \gamma_5) \Psi \quad (19a)$$

or

$$L^{(2)} = \frac{1}{4} F_{\mu\nu}(A) F_{\mu\nu}(A) + \Psi^\dagger (\not{p} + i \not{A} \gamma_5) \Psi. \quad (19b)$$

The former Lagrangian is non-Hermitian while the latter does not have a compact axial gauge invariance.

1.3 2 + 2 Dimensions

In 2 + 2 dimensions, spinors can be both Majorana and Weyl [6]. Spinors take the form

$$\Psi = \begin{pmatrix} \phi_a \\ \chi^{\dot{a}} \end{pmatrix} \quad \bar{\Psi} = (i\epsilon^{ab}\phi_b^*, i\epsilon_{\dot{a}\dot{b}}\chi^{\dot{b}*}) \quad (20a, b)$$

$$\Psi_C = \begin{pmatrix} \bar{\phi}_a \\ \bar{\chi}^{\dot{a}} \end{pmatrix}, \quad \bar{\Psi}_C = (\phi^a, \chi_{\dot{a}})$$

and the two simplest SUSY algebras are

$$\{q_a, r_{\dot{b}}\} = 2(\sigma_\mu)_{a\dot{b}} P^\mu \quad (\text{no central charge}) \quad (21a)$$

and

$$\{Q, \bar{Q}\} = 2\gamma^\mu P_\mu + Z + Z_5\gamma_5 \quad (21b)$$

for Majorana and Dirac spinorial generators $Q = \begin{pmatrix} q_a \\ r^{\dot{a}} \end{pmatrix}$ respectively. In [6] it is shown that both of these algebras can be rewritten in terms of Fermionic creation and annihilation operators that generate a Hilbert space with negative norm states; this is taken to indicate that SUSY is incompatible with a 2 + 2 dimensional space.

1.4 3 + 0 Dimensions

In three dimensional Euclidean space, the simplest SUSY algebra is [7,8]

$$\{Q, Q^\dagger\} = \vec{\sigma} \cdot \vec{p} + Z \quad (22)$$

where Q is a two component Dirac spinorial generator, $\vec{\sigma}$ is a set of Pauli matrices and Z is a central charge operator. Forming a superspace with coordinates $(x^\mu, \zeta, \theta_i$ and $\theta_i^\dagger)$ allows one to make the identifications

$$Q_i = \frac{\partial}{\partial \theta_i^\dagger} - \frac{i}{2} (\vec{\sigma} \cdot \vec{\nabla} \theta)_i - \frac{i}{2} \left(\theta \frac{\partial}{\partial \zeta} \right)_i \quad (23a)$$

$$P_\mu = -i \frac{\partial}{\partial x^\mu}, \quad Z = -i \frac{\partial}{\partial \zeta}. \quad (23b, c)$$

This makes it possible to formulate supersymmetric models in 3+0 dimensions which are analogous to both the Wess-Zumino and $N = 1$ gauge models in 3 + 1 dimensions. A similar analysis can be applied to $N = 2$ supersymmetric models in 2 + 1 dimensions. Dimensional reduction can be used to establish a relationship between supersymmetric models in 3 + 1 dimensions and three dimensional supersymmetric models.

We note that just in (8) and (15), in 2 + 1 dimensions the central charge in extended SUSY models provides a lower bound for the momentum, while in 3 + 0 dimensions, it provides an upper bound.

An analysis of supersymmetry in five dimensions [7] reveals that much as in four dimensions, no time dimensions implies an upper bound on momentum; one time dimension implies a lower bound on momentum and two time dimensions implies that for all momentum, negative norm states occur.

2 Constant Curvature Space SUSY Analysis

2.1 S_2

The simplest SUSY algebra [9] associated with the two dimensional surface of a sphere embedded in three dimensions is

$$\{Q_i, Q_j\} = 0 \quad , \quad \{Q_i, Q_j^\dagger\} = Z\delta_{ij} - 2\vec{\sigma}_{ij} \cdot \vec{P} \quad (24)$$

$$[J^a, Q] = -\frac{1}{2}\sigma^a Q, \quad [J^a, J^b] = i\epsilon^{abc}J^c, \quad [Z, Q] = -Q$$

(Note that Z is no longer a “central charge” as it does not commute with Q .) To examine representations of this superalgebra, we define a state $|I\rangle$ such that

$$J^2|I\rangle = j(j+1)|I\rangle, \quad J_3|I\rangle = m|I\rangle \quad (25)$$

$$Z|I\rangle = \zeta|I\rangle, \quad Q|I\rangle = 0.$$

Now if $|i\rangle = Q_i^\dagger|I\rangle$ and $|F\rangle = Q_1^\dagger Q_2^\dagger|I\rangle$, we find that $\langle 1|1\rangle = (\zeta + 2m)$, $\langle 2|2\rangle = \zeta - 2m$, $\langle F|F\rangle = (\zeta - 2j)(\zeta + 2j + 2)$, showing that a positive definite Hilbert space occurs if

$$\zeta \geq 2j. \quad (26)$$

A model invariant under transformations generated by the SUSY algebra of (22) is

$$S = \int dA \left\{ \frac{1}{2}\Psi^\dagger(\sigma \cdot L + x)\Psi - \Phi^* \left(L^2 + x(1-x) \right) \Phi - \frac{1}{4}F^*F \right. \quad (27)$$

$$\left. + \lambda_N \left(2(1-2x)\Phi^*\Phi - (F^*\Phi + F\Phi^*) - \Psi^\dagger\Psi \right)^N \right\};$$

the off mass shell transformations are

$$\delta\Phi = \xi^\dagger\Psi, \quad \delta\Psi = 2(\sigma \cdot L + 1 - x)\Phi\xi - F\xi, \quad \delta F = -2\xi^\dagger(\sigma \cdot L + x)\Psi \quad (28a-c)$$

$$\delta_Z\Phi = [2(1-2x)\Phi - F], \quad \delta_Z\Psi = [1 + 2\sigma \cdot L]\Psi, \quad \delta_Z F = -4[L^2 + x(1-x)]\Phi + 2xF. \quad (28d-f)$$

The symmetries of (28d-f) are in fact new symmetries.

A superspace representation of the algebra of (22) is provided by

$$Q = (\sigma \cdot \vec{r} + \zeta)\frac{\partial}{\partial\theta^\dagger} - \left(\frac{\partial}{\partial\zeta} - \sigma \cdot \nabla \right) \theta \quad (29a)$$

$$Q^\dagger = \frac{\partial}{\partial\theta}(\sigma \cdot r + \zeta) + \theta^\dagger \left(\frac{\partial}{\partial\zeta} - \sigma \cdot \nabla \right) \quad (29b)$$

$$J^a = -i(r \times \nabla)^a + \frac{1}{2} \left(\theta^\dagger \sigma^a \frac{\partial}{\partial\theta^\dagger} + \frac{\partial}{\partial\theta} \sigma^a \theta \right) \quad (29c)$$

$$Z = -\theta^\dagger \frac{\partial}{\partial\theta^\dagger} + \theta \frac{\partial}{\partial\theta}. \quad (29d)$$

We note that under a supersymmetry transformation generated by (29)

$$\delta r^a = \epsilon^\dagger \sigma^a \theta + \theta^\dagger \sigma^a \epsilon \quad (30a)$$

$$\delta \theta = \vec{\sigma} \cdot \vec{r} \epsilon + \zeta \epsilon. \quad (30b)$$

Furthermore, we see that

$$\left[Q, \vec{r}^2 - \zeta^2 - 2\theta^\dagger \theta \right] = 0 \quad (31a)$$

$$\left[Q, \theta^\dagger \frac{\partial}{\partial \theta^\dagger} + \theta \frac{\partial}{\partial \theta} + \vec{r} \cdot \vec{\nabla} + \zeta \frac{\partial}{\partial \zeta} \right] = 0. \quad (31b)$$

Currently we are attempting to formulate the model of (25) in terms of superfields using the superspace realizations (29) of the generators and (31a,b).

2.2 AdS_2

On AdS_2 we have the algebra

$$[J_{ab}, J_{cd}] = \eta_{ac} J_{bd} - \eta_{bc} J_{ad} + \eta_{bd} J_{ac} - \eta_{ad} J_{bc} \quad (32a)$$

$$\{Q, \tilde{Q}\} = 2\Sigma^{ab} J_{ab} \quad (\tilde{Q} = Q\gamma_2) \quad (32b)$$

$$\{J_{ab}, Q\} = -\Sigma_{ab} Q \quad (32c)$$

(Q is Majorana, $\eta_{ab} = \text{diag}(+, -, +)$, $\gamma_a \gamma_b = -\eta_{ab} - i\epsilon^{abc} \gamma_c$, $\Sigma_{ab} = \frac{1}{4} [\gamma_a, \gamma_b]$.) This algebra can be realized by

$$J_{ab} = \frac{\partial}{\partial \theta} \Sigma_{ab} \theta - (x_a \partial_b - x_b \partial_a) \quad (33a)$$

$$Q = \gamma^a \partial_a \theta + \gamma^a x_a \frac{\partial}{\partial \theta} \quad (33b)$$

$$\tilde{Q} = -\tilde{\theta} \gamma^a \partial_a + \frac{\partial}{\partial \theta} \gamma^a x_a \quad (33c)$$

where θ is a two component Grassmann Majorana spinor. We also define

$$D = -\gamma^a \partial_a \theta + \gamma^a x_a \frac{\partial}{\partial \tilde{\theta}} \quad (34a)$$

$$\tilde{D} = \tilde{\theta} \gamma^a \partial_a + \frac{\partial}{\partial \theta} \gamma^a x_a. \quad (34b)$$

We note that

$$\left[Q_i, x^a \partial_a + \theta_j \frac{\partial}{\partial \theta_j} \right] = 0 \quad (35a)$$

$$\left[Q_i, x^a x_a - \tilde{\theta} \theta \right] = 0. \quad (35b)$$

Applying the condition

$$\Delta \Phi = \omega \Phi \quad (36)$$

so that if

$$\Phi = \phi + \tilde{\lambda}\theta + F\tilde{\theta}\theta \quad (37)$$

then we have $(x \cdot \partial - \omega) \phi = (x \cdot \partial + 1 - \omega)\lambda = (x \cdot \partial + 2 - \omega)F = 0$.

Some suitable supersymmetric actions are

$$S_1 = \int d^3x d^2\theta \delta(x^2 - \tilde{\theta}\theta - a^2) \Phi(\tilde{D}D + \rho)\Phi \quad (38a)$$

$$S_2 = \int d^3x d^2\theta \delta(x^2 - \tilde{\theta}\theta - a^2) (\tilde{D}\Phi D\Phi + \rho\Phi^2) \quad (38b)$$

$$S_3 = \int d^3x d^2\theta \delta(x^2 - \tilde{\theta}\theta - a^2) (\Phi\tilde{Q}Q\Phi + \rho\Phi^2) \quad (38c)$$

$$S_4 = \int d^3x d^2\theta \delta(x^2 - \tilde{\theta}\theta - a^2) (\tilde{Q}\Phi Q\Phi + \rho\Phi^2). \quad (38d)$$

In component form, for example, (38a) reduces to

$$\begin{aligned} S_1 = \int d^3x \left\{ \delta(x^2 - a^2) \left[F(-2x^2F + 2(\rho - 1)\phi) \right. \right. \\ \left. \left. + \frac{1}{2x^2}\phi(L^{ab}L_{ab} + 2\omega(1 + \omega))\phi - \tilde{\lambda}\left(\Sigma^{ab}L_{ab} - \frac{3 - \rho}{2}\right)\lambda \right] \right. \\ \left. + \delta'(x^2 - a^2) \left[2\phi\left(x^2F + \left(\frac{\rho}{2} - \omega\right)\phi\right) \right] \right\}. \end{aligned} \quad (39)$$

Other supersymmetric actions on AdS_2 can be devised in component form; for example

$$\begin{aligned} S = \int d^2x \left\{ \left[\tilde{\Psi}(\Sigma^{ab}L_{ab} + \chi)\Phi + \Phi\left(\frac{1}{2}L^{ab}L_{ab} + \chi(1 + \chi)\right)\Phi \right. \right. \\ \left. \left. - FF \right] + \lambda_N \left[(1 + 2x)\Phi\Phi + \tilde{\Psi}\Psi + 2\Phi F \right]^N \right\} \end{aligned} \quad (40)$$

possesses the invariance

$$\delta\Psi = \left[(\Sigma^{ab}L_{ab} - (1 + x))\Phi - F \right] \xi \quad (41a)$$

$$\delta\Phi = \tilde{\xi}\Psi, \quad \delta F = -\tilde{\xi}(\Sigma^{ab}L_{ab} + \chi)\Psi. \quad (41b, c)$$

The relation between the models of (38) and (40) is not apparent.

The role of ζ in (29) is not at all clear. However, it is necessary to introduce ζ in order for Q to be the “square root” of the non-Abelian operator J^a .
